Fruit Flies in Africa

Many tropical or subtropical areas of the world, as well as some temperate areas, are confronted in a similar way with the problems arising from fruit flies (Diptera, Tephritidae), although each area presents, in this respect, a group of species which is peculiar for it. The species most harmful to agriculture are responsible for direct damage, but also for losses to export markets related to the quarantine restrictions, which can be considerable. This document presents the advantage of showing the diversity of the recent studies devoted to this group of pests and the principal orientations of these works. Thirteen papers dedicated to these pests are collected in this special issue Fruits flies in Africa. Five of them focus on the fruit flies biology; two articles concern the polymorphism of the allozymes within the populations of the *Ceratis* sp. in the Mediterranean basin; control methods are presented in four documents while populations' displacements and interspecies competition receive special care in the two last articles.

principal orientations of these works. Thirteen papers dedicated to these pests are collected in this special issue Fruits flies in Africa.
